Iguana X Monitoring, APIs & Logging For Operational Visibility

Meer Ushter & John Qi

Why business teams should care about Alerts

In production, Alerts are not just a developer convenience — they are an operating model.

The business translation

Failed ADT message	Delayed Patient Data
Queue Backlog	Downstream Failing behind
Inactive message	Work silently stopped

Start with built-in monitoring and notifications

IguanaX notifications cover the health checks most teams need first.

Errors

Trigger when an error message is generated in component logs.
Business meaning: Failure visible now

Inactivity

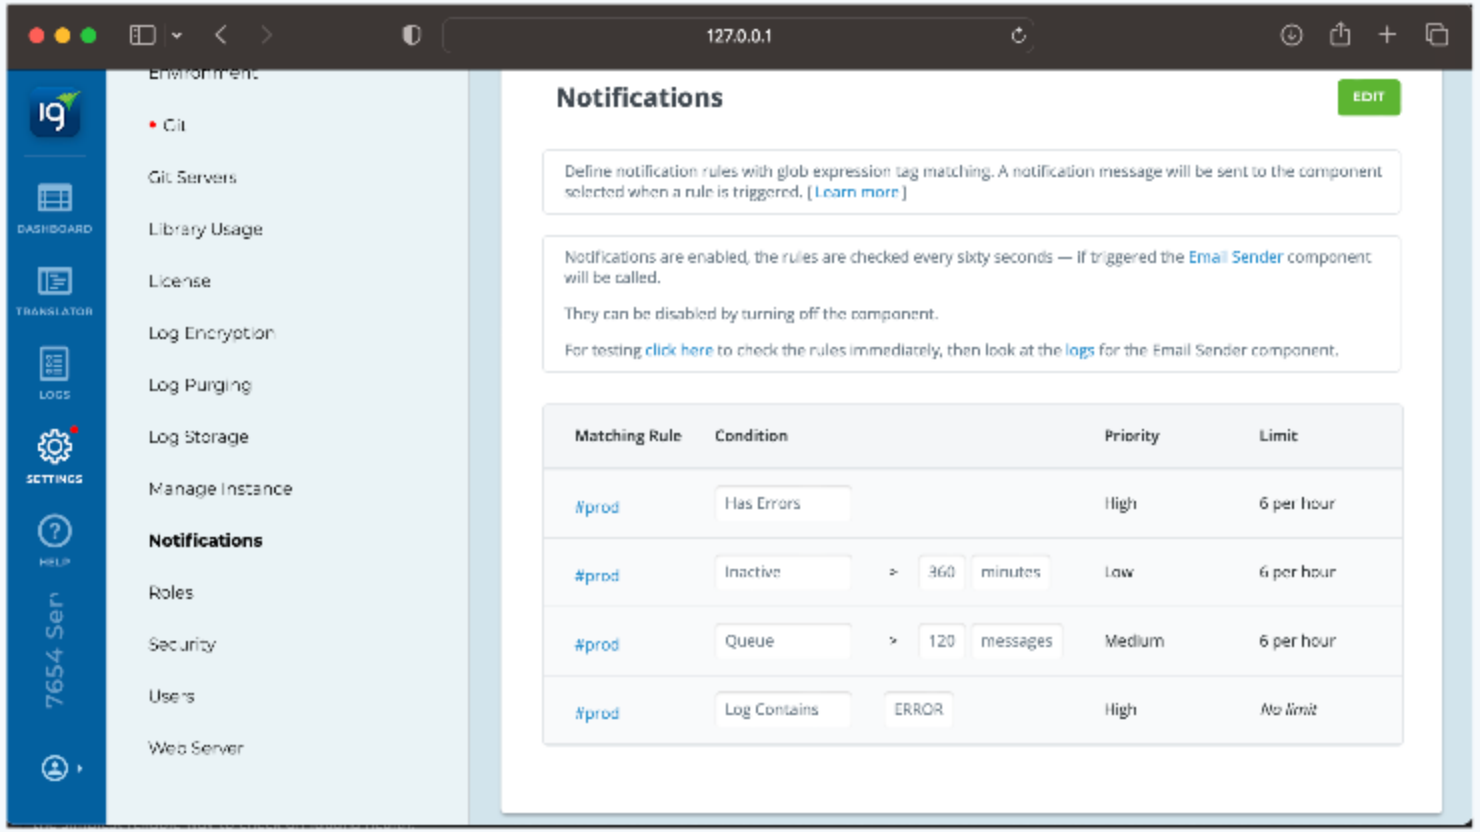

Trigger when a component has not processed messages in the time window.
Business meaning: Silent upstream issue

Log Contains

Trigger when logs contain a string or regex pattern.
Business meaning: Custom signal

Queue

Trigger when queue count exceeds a configured threshold.
Business meaning: Backlog before outage

Alert workflow: from Iguana signal to team response

The notification system turns health signals into Slack, email, or other team workflows.

Reliable pattern

A rule is triggered, a notification log is generated, and a notifier component delivers the message.

Practical result

The team receives a message with component, condition, priority, and a link back to logs.

Email notifications: dependable audit trail

Use email when alerts need to be shared, archived, or reviewed later.

Best fit

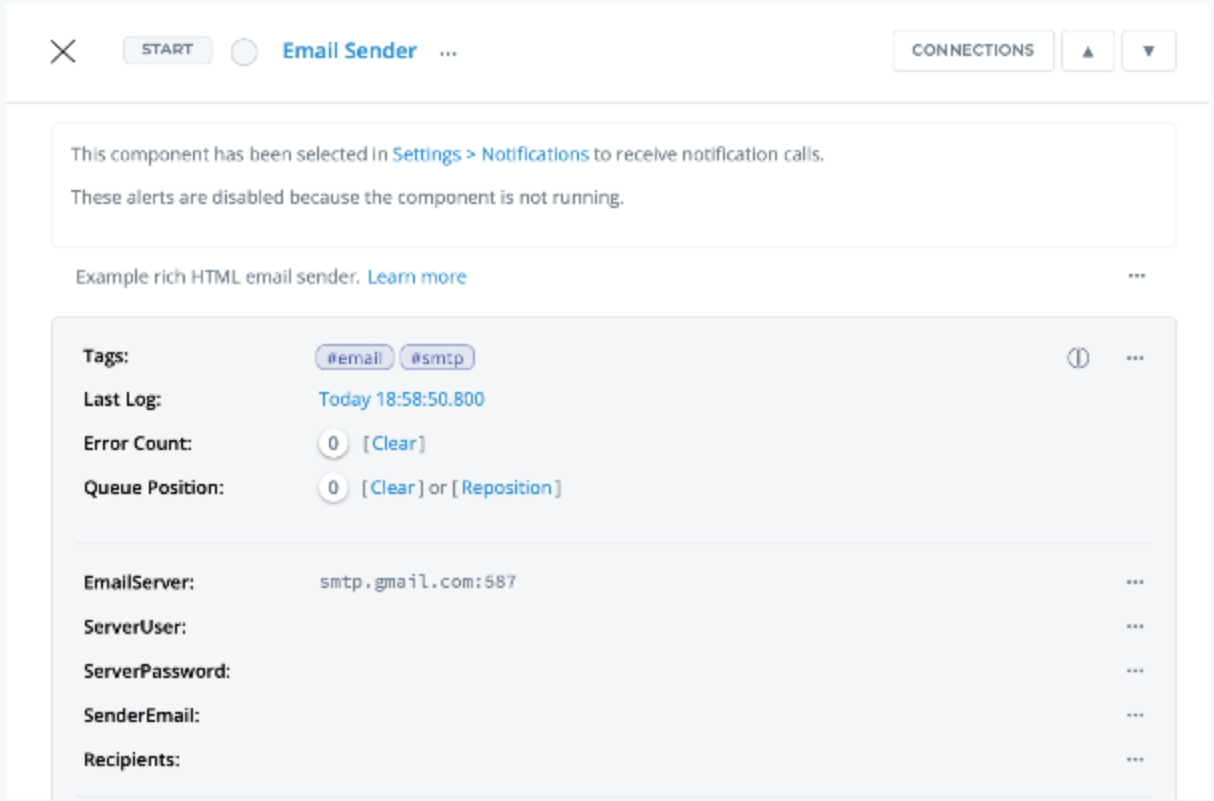

- On-call summaries
- Compliance or audit trails
- Cross-team distribution lists

How it is configured

The Email Sender component uses SMTP. Configure server, user, password, sender, and recipients in custom fields.

What to include

- Component and environment
- Condition and threshold
- Link to logs

Slack notifications: real-time response

Use Slack when the team needs to see, discuss, and own the issue immediately.

Best fit

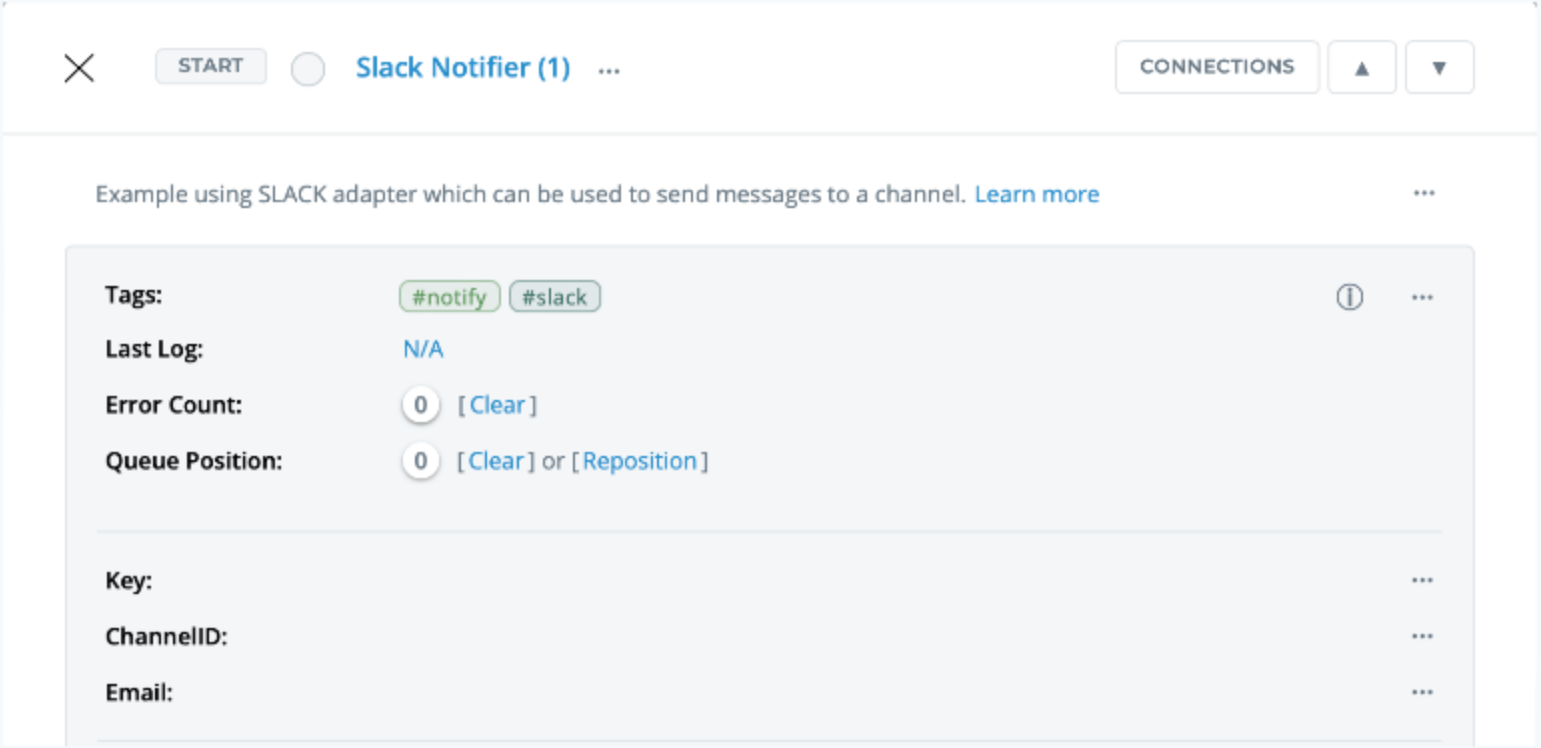

- Production war-room channel
- Ease of Collaboration
- Fast ownership and handoff

Setup essentials

- Create a Slack app
- Add Permissions
- Install to workspace
- Use Bot User OAuth Token

Delivery essentials

- Put the token in the notifier key
- Use a public channel ID
- Optionally tag a user by email
- Keep messages short and actionable

How We Can Enhance Current Alerts

Some health questions are not single-rule alerts. They require details

Why a normal alert is not enough

- The signal is a trend over time
- The answer needs top offenders and exact log detail
- The output should be a summarized health report

Example notification

Component: example-component
Condition: error threshold exceeded
Action: review component logs

The core automation pattern

Every useful API automation follows the same simple loop.

Why this matters?

Once operations become code, they become repeatable, testable, auditable, and reusable across environments.

Log API as the practical demo

Use logs as the operational data source; use the API to query and retrieve details.

Sample /logs/retrieve call remote

```
-- Remote API session workflow
-- Credentials come from protected fields
local cookie = login(credentials)
local logs = retrieveLogs(
  baseUrl, componentId, cookie
)
logout(baseUrl, cookie)

-- See the Log API example repository
-- for the implemented request handling.
```

Sample /logs/retrieve call Local

```
-- Within an authorized component
local logs = iguana.call{
  api = '/logs/retrieve',
  data = {
    component = componentId,
    tags = '#error',
    limit = 5
  },
  live = true
}
```

Example incident flow

How the Log API demo maps to a real production response.

Notification Rule Triggered

Node B queue grows while ADT messages arrive.

Receiver Receives message

/logs/retrieve finds #error and recent failures.

Log API queries logs

Log detail are received

Sender Generates Message

Using Log Api details message is generated to send

Slack + email sent

#iguanax-alerts-prod receives alert; on-call gets details.

The value is not the alert itself — it is the time saved between signal, ownership, and resolution.

Key takeaway

Logs give visibility.
APIs turn visibility into action.

Using the Log API as the demo, the same pattern can support monitoring, troubleshooting, alerting, dashboards, and integrations across IguanaX.

Q&A
